CS 550: Programming Project 1

Collaboration Policy. Assignments will be done individually: each student must hand in their own answers. It is acceptable for students to collaborate in understanding the material but not in solving the problems or programming. Use of the Internet is allowed, but should not include searching for existing solutions.

Under absolutely no circumstances code can be exchanged between students. If some code was shown in the course material or class, it can be used, but it must be obtained from Canvas, the instructor or the Teaching Assistant.

Assignments from previous offerings of the course must not be re-used. Violations will be penalized appropriately.

Late Policy. No late submissions will be allowed without consent from the instructor. If urgent or unusual circumstances prohibit you from submitting a homework assignment in time, please e-mail the instructor.

Deliverable. Submit on Canvas a zip file containing:

1. a pdf file describing what you did including the screenshots,
2. a file with the source code named fibonacci.s (not executables, project files etc.).

Requirements

1. Implement LEGv8 code in DS-5 that accepts a number n, and produces the nth Fibonacci number using the efficient O(n) version. The number should be in the .data segment of your program. See the document "Project 1: Fibonacci Numbers" for details on the algorithm.
2. Your code must print the nth Fibonacci number using printf.
3. Run the program in debugging mode. Step through the execution and stop right before and after the link register changes value. At these points take screenshots, showing the debug window with the registers. The second screenshot should show the highlighted register indicating that its value has changed. Include the screenshots in the pdf file.
4. If your code does not compile, you will get 0 credit. Make sure that your code compiles to earn partial credit.
